Program Execution

• Direct Unix execution of a program
  
  - Add the hashbang (#!) line as the first line, two approaches
  - `#!/usr/bin/python`
  - `#!/usr/bin/env python`

  - Sometimes specify `python3` to make sure we're running Python 3
  - File must be flagged as executable (chmod a+x) and have line endings
  - Then you can say: `$ ./filename.py arg1 ...`

• Executing the Python compiler/interpreter
  
  - `$ python filename.py arg1 ...`

• Same results either way
Accepting Command-Line Parameters

- Parameters are received as a list of strings entitled `sys.argv`
- Need to `import sys` first
- `sys.argv[0]` is the name of the program as executed
  - Executing as `./hw01.py` or `hw01.py` will be passed as different strings
- `sys.argv[n]` is the nth argument
- `sys.executable` is the python executable being run
Modules and Packages

• Python allows you to import code from other files, even your own
• A module is a collection of definitions
• A package is an organized collection of modules
• Modules can be
  - a separate python file
  - a separate C library that is written to be used with Python
  - a built-in module contained in the interpreter
  - a module installed by the user (via conda or pip)
• All types use the same import syntax
What is the purpose of having modules or packages?

- Code reuse: makes life easier because others have written solutions to various problems
- Generally forces an organization of code that works together
- Standardizes interfaces; easier maintenance
- Encourages robustness, testing code

- This does take time so don't always create a module or package
  - If you're going to use a method once, it's not worth putting it in a module
  - If you're using the same methods over and over in (especially in different projects), a module or package makes sense
Importing modules

- `import <module>`
- `import <module> as <another-identifier>`
- `from <module> import <identifier-list>`
- `from <module> import <identifier> as <another-identifier>, ...`

- `import imports from the top, from ... import imports "inner" names`
- Need to use the qualified names when using import (`foo.bar.mymethod`)
- `as clause renames` the imported name
Using an imported module

- Import module, and call functions with **fully qualified** name
  ```python
  import math
  math.log10(100)
  math.sqrt(196)
  ```

- Import module into current namespace and use **unqualified** name
  ```python
  from math import log10, sqrt
  log10(100)
  sqrt(196)
  ```
Using code as a module, too

- def main():
  print("Running the main function")
  main() # now, we're calling main

- Generally, when we import a module, we don’t want it to execute code.
- import my_code # prints "Running the main function"

- Whenever a module is imported, Python creates a special variable in the module called __name__ whose value is the name of the imported module.

- We can change the final lines of our programs to:
  - if __name__ == '__main__':
    main()

- main() only runs when the file is run as a script!
Assignment 4

- Books in German
- Reading & Writing Files
- Iterators
- Converting certain values
- String Formatting
- CSCI 503 students compute and output statistics to compare authors
How does import work?

• When a module/package is imported, Python
  - Searches for the module/package
    • Sometimes this is internal
    • Otherwise, there are directory paths (environment variable `PYTHONPATH`) that python searches (accessible via `sys.path`)
  - Loads it
    • This will run the code in specified module (or `__init__.py` for a package)
  - Binds the loaded names to a namespace
Namespaces

• An import defines a separate namespace while from...import adds names to the current namespace

• Four levels of namespace
  - builtins: names exposed internally in python
  - global: names defined at the outermost level (wrt functions)
  - local: names defined in the current function
  - enclosing: names defined in the outer function (when nesting functions)

• def foo():
  a = 12
  def bar():
    print("This is a:", a)

  a is in the enclosing namespace of bar
Namespaces

- Namespace is basically a dictionary with names and their values
- Accessing namespaces
  - `__builtins__`, `globals()`, `locals()`
- Examine contents of a namespace:
  - `dir(<namespace>)`
- Python checks for a name in the sequence:
  - local, enclosing, global, builtins
- To access names in outer scopes, use `global` (global) and `nonlocal` (enclosing) declarations
Wildcard imports

- Wildcard imports import all names (non-private) in the module
- What about
  - from math import *
- Avoid this!
  - Unclear which names are available!
  - Confuses someone reading your code
  - Think about packages that define the same names!
- Allowed if republishing internal interface (e.g. in a package, you're exposing functions defined in different modules)
Import Guidelines (from PEP 8)

• Imports should be on separate lines
  - import sys, os
  - import sys
    import os

• When importing multiple names from the same package, do use same line
  - from subprocess import Popen, PIPE

• Imports should be at the top of the file (order: standard, third-party, local)
• Avoid wildcard imports in most cases
Conditional or Dynamic Imports

• Best practice is to put all imports at the beginning of the py file
• Sometimes, a conditional import is required
  - if sys.version_info >= [3,7]:
    OrderedDict = dict
  else:
    from collections import OrderedDict
• Can also dynamically load a module
  - import importlib
  - importlib.import_module("collections")
  - The __import__ method can also be used
Absolute & Relative Imports

• Fully qualified names
  - import foo.bar.submodule

• Relative names
  - import .submodule

• Absolute imports recommended but relative imports acceptable
Import Abbreviation Conventions

• Some libraries and users have developed particular conventions
  • import numpy as np
  • import pandas as pd
  • import matplotlib.pyplot as plt
• This can lead to problems:
  - sympy and scipy were both abbreviated sp for a while…
Reloading a Module?

• If you re-import a module, what happens?
  - import my_module
    my_module.SECRET_NUMBER # 42
  - Change the definition of SECRET_NUMBER to 14
    - import my_module
      my_module.SECRET_NUMBER # Still 42!

• Modules are **cached** so they are not reloaded on each import call
• Can reload a module via `importlib.reload(<module>)`
• Be careful because **dependencies** will persist! (Order matters)
Python Packages

- A package is basically a collection of modules in a directory subtree
- Structures a module namespace by allowing dotted names
- Example:
  - test_pkg/
    __init__.py
    foo.py
    bar.py
    baz/
      fun.py
- For packages that are to be executed as scripts, __main__.py can also be added
What's `__init__.py` used for?

- Used to be required to identify a Python package (< 3.3)
- Now, only required if a package (or sub-package) needs to run some initialization when it is loaded
- Can be used to specify metadata
- Can be used to import submodule to make available without further import
  - `from . import <submodule>`
- Can be used to specify which names exposed on import
  - underscore names (`_internal_function`) not exposed by default
  - `__all__` list can further restrict, sets up an "interface" (applies to wildcard)
What is __main__.py used for?

- Remember for a module, when it is run as the main script, its __name__ is __main__
- Similar idea for packages
- Used as the entry point of a package when the package is being run (e.g. via `python -m`)
  - `python -m test_pkg` runs the code in __main__.py of the package
Example
Finding Packages

• Python Package Index (PyPI) is the standard repository (https://pypi.org) and pip (pip installs packages) is the official python package installer
  - Types of distribution: source (sdist) and wheels (binaries)
  - Each package can specify dependencies
  - Creating a PyPI package requires adding some metadata

• Anaconda is a package index, conda is a package manager
  - conda is language-agnostic (not only Python)
  - solves dependencies
  - conda deals with non-Python dependencies
  - has different channels: default, conda-forge (community-led)
Installing Packages

- pip install <package-name>
- conda install <package-name>

- In Jupyter use:
  - %pip install <package-name>
  - %conda install <package-name>

- Arguments can be multiple packages
- Be careful! Security exploits using package installation and dependencies (e.g. Alex Birsan)
Environments

- Both pip and conda support environments
  - venv
  - conda env
- Idea is that you can create different environments for different work
  - environment for cs503
  - environment for research
  - environment for each project
Object-Oriented Programming
Object-Oriented Programming Concepts

• ?
Object-Oriented Programming Concepts

- Abstraction: simplify, hide implementation details, don't repeat yourself
- Encapsulation: represent an entity fully, keep attributes and methods together
- Inheritance: reuse (don't reinvent the wheel), specialization
- Polymorphism: methods are handled by a single interface with different implementations (overriding)
Object-Oriented Programming Concepts

- **Abstraction**: simplify, hide implementation details, don't repeat yourself
- **Encapsulation**: represent an entity fully, keep attributes and methods together
- **Inheritance**: reuse (don't reinvent the wheel), specialization
- **Polymorphism**: methods are handled by a single interface with different implementations (overriding)
Vehicle Example

• Suppose we are implementing a city simulation, and want to model vehicles driving on the road

• How do we represent a vehicle?
  - Information (attributes)
  - Methods (actions)
Vehicle Example

• Suppose we are implementing a city simulation, and want to model vehicles driving on the road

• How do we represent a vehicle?
  - Information (attributes): make, model, year, color, num_doors, engine_type, mileage, acceleration, top_speed, braking_speed
  - Methods (actions): compute_estimated_value(), drive(num_seconds, acceleration), turn_left(), turn_right(), change_lane(dir), brake(), check_collision(other_vehicle)
Other Entities

- Road, Person, Building, ParkingLot
- Some of these interact with a Vehicle, some don't
- We want to store information associated with entities in a structured way
  - Building probably won't store anything about cars
  - Road should not store each car's make/model
  - …but we may have an association where a Road object keeps track of the cars currently driving on it
Object-Oriented Design

• There is a lot more than can be said about how to best define classes and the relationship between different classes
• It's not easy to do this well!
• Software Engineering
• Entity Relationship (ER) Diagrams
• Difference between Object-Oriented Model and ER Model
Class vs. Instance

• A **class** is a blueprint for creating instances
  - e.g. Vehicle

• An **instance** is an single object created from a class
  - e.g. 2000 Red Toyota Camry
  - Each object has its own attributes
  - Instance methods produce results unique to each particular instance
Classes and Instances in Python

• Class Definition:
  ```python
  class Vehicle:
    def __init__(self, make, model, year, color):
      self.make = make
      self.model = model
      self.year = year
      self.color = color

    def age(self):
      return 2021 - self.year
  ```

• Instances:
  ```python
  car1 = Vehicle('Toyota', 'Camry', 2000, 'red')
  car2 = Vehicle('Dodge', 'Caravan', 2015, 'gray')
  ```
Test 1
