

# Programming Principles in Python (CSCI 503/490)

---

## Object-Oriented Programming

Dr. David Koop

# Reloading a Module?

---

- If you re-import a module, what happens?
  - `import my_module`  
`my_module.SECRET_NUMBER # 42`
  - Change the definition of `SECRET_NUMBER` to 14
  - `import my_module`  
`my_module.SECRET_NUMBER # Still 42!`
- Modules are **cached** so they are not reloaded on each import call
- Can reload a module via `importlib.reload(<module>)`
- Be careful because **dependencies** will persist! (Order matters)

# Python Packages

---

- A package is basically a collection of modules in a directory subtree
- Structures a module namespace by allowing dotted names
- Example:
  - test\_pkg/
    - \_\_init\_\_.py
    - foo.py
    - bar.py
    - baz/
      - fun.py
- For packages that are to be executed as scripts, `__main__.py` can also be added

# Finding & Installing Packages

---

- Python Package Index (PyPI) is the standard repository (<https://pypi.org>) and pip (pip installs packages) is the official python package installer
  - `%pip install <package-name>`
- Anaconda is a package index, conda is a package manager
  - `%conda install <package-name>`
- Create **environments** for different work
- Newer tools:
  - uv is a faster version of pip
  - pixi is a faster version of conda with uv integration
  - Both are project-based (~one environment per project)

# Classes and Instances in Python

---

- Class Definition:

```
- class Vehicle:
    def __init__(self, make, model, year, color):
        self.make = make
        self.model = model
        self.year = year
        self.color = color

    def age(self):
        return 2022 - self.year
```

- Instances:

```
- car1 = Vehicle('Toyota', 'Camry', 2000, 'red')
- car2 = Vehicle('Dodge', 'Caravan', 2015, 'gray')
```

# Visibility

---

- In some languages, encapsulation allows certain attributes and methods to be hidden from those using an instance
- public (visible/available) vs. private (internal only)
- Python does not have visibility descriptors, but rather conventions (PEP8)
  - Attributes & methods with a leading underscore (\_) are intended as private
  - Others are public
  - You can still access private names if you want but generally **shouldn't**:
    - `print(car1._color_hex)`
  - Double underscores leads to **name mangling**:  
`self.__internal_vin` is stored at `self._Vehicle__internal_vin`

# Assignment 5

---

- Due next Monday
- Same Pokemon data as A3
- Scripts, modules, packages
- Command-line program

# Quiz Wednesday

---

- Quiz on Object-Oriented Programming

# Representation methods

---

- Printing objects:
  - `print(car1)` # `<__main__.Vehicle object at 0x7efc087c6b20>`
- "Dunder-methods": `__init__`
- Two for representing objects:
  - `__str__`: human-readable
  - `__repr__`: official, machine-readable
- ```
>>> now = datetime.datetime.now()
>>> now.__str__()
'2020-12-27 22:28:00.324317'
>>> now.__repr__()
'datetime.datetime(2020, 12, 27, 22, 28, 0, 324317)'
```

[<https://www.journaldev.com/22460/python-str-repr-functions>]

# Representation methods

---

- Car example:

- `class Vehicle:`  
    ...  
    `def __str__(self):`  
        `return f'{self.year} {self.make} {self.model}'`

- Don't call `print` in this method! Return a string

- When using, don't call directly, use `str` or `repr`

- `str(car1)`

- `print` internally calls `__str__`

- `print(car1)`

# Other Dunder Methods

---

- `__eq__(<other>)`: return `True` if two objects are equal
- `__lt__(<other>)`: return `True` if object `<` other
- Collections:
  - `__len__()`: return number of items
  - `__contains__(item)`: return `True` if collection contains `item`
  - `__iter__()`: returns iterator
- Sequence + dict
  - `__getitem__(index)`: return item at `index` (which could be a key)
- + More

# Properties

---

- Common pattern is getters and setters:
  - `def age(self):`  
    `return 2024 - self.year`
  - `def set_age(self, age):`  
    `self.year = 2024 - age`
- In some sense, this is no different than `year` except that we don't want to store `age` separate from `year` (they should be linked)
- Properties allow transformations and checks but are accessed like attributes
- `@property`  
    `def age(self):`  
        `return 2024 - self.year`
- `car1.age # 15`

# Properties

---

- Can also define setters
- Syntax is a bit strange, want to link the two: `@<property-name>.setter`
- Method has the same name as the property: How?
- Decorators (`@<decorator-name>`) do some magic
- `@property`  

```
def age(self):  
    return 2024 - self.year
```
- `@age.setter`  

```
def age(self, age):  
    self.year = 2024 - age
```
- `car1.age = 15`

# Properties

---

- Add validity checks!
- First car was 1885 so let's not allow ages greater than that (or negative ages)
- `@age.setter`

```
def age(self, age):  
    if age < 0 or age > 2024 - 1885:  
        print("Invalid age, will not set")  
    else:  
        self.year = 2024 - age
```
- Better: raise exception (later)

# Class Attributes

---

- We can add class attributes inside the class indentation:
- Access by prefixing with **class name** or `self`

```
- class Vehicle:
    CURRENT_YEAR = 2024
    ...
    @age.setter
    def age(self, age):
        if age < 0 or age > Vehicle.CURRENT_YEAR - 1885:
            print("Invalid age, will not set")
        else:
            self.year = self.CURRENT_YEAR - age
```

- Constants should be CAPITALIZED
- This is not a great constant! (`EARLIEST_YEAR = 1885` would be!)

# Inheritance

---

- Is-a relationship: Car is a Vehicle, Truck is a Vehicle
- Make sure it isn't composition (has-a) relationship: Vehicle has wheels, Vehicle has a steering wheel
- Subclass is specialization of base class (superclass)
  - Car is a subclass of Vehicle, Truck is a subclass of Vehicle
- Can have an entire hierarchy of classes (e.g. Chevy Bolt is subclass of Car which is a subclass of Vehicle)
- Single inheritance: only one base class
- Multiple inheritance: allows more than base class
  - Many languages don't support, Python does

# Subclass

---

- Just put superclass(-es) in parentheses after the class declaration
- ```
class Car(Vehicle):  
    def __init__(self, make, model, year, color, num_doors):  
        super().__init__(make, model, year, color)  
        self.num_doors = num_doors  
  
    def open_door(self):  
        ...
```
- `super()` is a special method that locates the base class
  - Constructor should call superclass constructor, then initialize its own extra attributes
  - Instance methods can use `super`, too

# Instance Attribute Conventions in Python

---

- Remember, the naming is the convention
- `public`: used anywhere
- `_protected`: used in class and subclasses
- `__private`: used only in the specific class
- Note that double underscores induce name mangling to strongly discourage access in other entities

# Overriding Methods

---

- ```
class Rectangle:  
    def __init__(self, height,  
                  width):  
        self.h = height  
        self.w = width  
  
    def set_height(self, height):  
        self.h = height  
    def area(self):  
        return self.h * self.w
```
- ```
class Square(Rectangle):  
    def __init__(self, side):  
        super().__init__(side, side)  
  
    def set_height(self, height):  
        self.h = height  
        self.w = height
```

- ```
s = Square(4)
```
- ```
s.set_height(8)
```

  - Which method is called?
  - Polymorphism
  - Resolves according to inheritance hierarchy
- ```
s.area() # 64
```

  - If no method defined, goes up the inheritance hierarchy until found

# Operator Overloading

---

- More dunder methods (`__add__`, `__sub__`, `__mul__`, `__truediv__`)

- Example:

```
- class Square(Rectangle):  
    ...  
    @property  
    def side(self):  
        return self.h  
    def __add__(self, right):  
        return Square(self.side + right.side)  
    def __repr__(self):  
        return f'{self.__class__.__name__}({self.side})'  
  
new_square = Square(8) + Square(4)  
new_square # Square(12)
```

# Operator Overloading Restrictions

---

- Precedence cannot be changed by overloading. However, parentheses can be used to force evaluation order in an expression.
- The left-to-right or right-to-left grouping of an operator cannot be changed
- The “arity” of an operator—that is, whether it’s a unary or binary operator—cannot be changed.
- You cannot create new operators—only overload existing operators
- The meaning of how an operator works on objects of built-in types cannot be changed. You cannot change `+` so that it subtracts two integers
- Works only with objects of custom classes or with a mixture of an object of a custom class and an object of a built-in type.

[Deitel & Deitel]

# Left and Right Operands?

---

- `class Square(Rectangle):`  
    ...  
    `def __add__(self, right):`  
        `return Square(self.side + right)`

`Square(8) + 4 # Square(12)`  
`4 + Square(8) # error`

- Solution: Use `__radd__` and related operators
- `class Square(Rectangle):`

    ...  
    `def __radd__(self, left):`  
        `return Square(left + self.side)`

`4 + Square(8) # Square (12)`

# Ternary Operator

---

- In other languages: `a = b < 5 ? b + 5 : b - 5`
- Means: `if (b < 5) a = b + 5; else a = b - 5;`
- Kind of a weird construct, but can be a nice shortcut
- Python does this differently:
- `<value> if <condition> else <value>`
- Python Example: `a = b + 5 if b < 5 else b - 5`
- Reads so that the usual is listed first and the abnormal case is listed last
- "Usually this, else default to this other" (cases are pushed apart)

# Class and Static Methods

---

- Use `@classmethod` and `@staticmethod` decorators
- Difference: class methods receive class as argument, static methods do not

- ```
class Square(Rectangle):  
    DEFAULT_SIDE = 10  
    ...  
  
    @classmethod  
    def set_default_side(cls, s):  
        cls.DEFAULT_SIDE = s  
  
    @staticmethod  
    def set_default_side_static(s):  
        Square.DEFAULT_SIDE = s
```

# Class and Static Methods

---

- ```
class Square(Rectangle):  
    DEFAULT_SIDE = 10  
  
    def __init__(self, side=None):  
        if side is None:  
            side = self.DEFAULT_SIDE  
        super().__init__(side, side)  
    ...
```
- ```
Square.set_default_side(20)  
s2 = Square()  
s2.side # 20
```
- ```
Square.set_default_side_static(30)  
s3 = Square()  
s3.side # 30
```

# Class and Static Methods

---

- `class NewSquare(Square):`  
    `DEFAULT_SIDE = 100`
- `NewSquare.set_default_side(200)`  
    `s5 = NewSquare()`  
    `s5.side # 200`
- `NewSquare.set_default_side_static(300)`  
    `s6 = NewSquare()`  
    `s6.side # !!! 200 !!!`
- Why?
  - The static method sets `Square.DEFAULT_SIDE` not the `NewSquare.DEFAULT_SIDE`
  - `self.DEFAULT_SIDE` resolves to `NewSquare.DEFAULT_SIDE`
