

Programming Principles in Python (CSCI 503/490)

Object-Oriented Programming

Dr. David Koop

Modules and Packages

- Python allows you to import code from other files, even your own
- A **module** is a collection of definitions
- A **package** is an organized collection of modules
- Modules can be
 - a separate python file
 - a separate C library that is written to be used with Python
 - a built-in module contained in the interpreter
 - a module installed by the user (via conda or pip)
- All types use the same import syntax

What is the purpose of having modules or packages?

- Code reuse: makes life easier because others have written solutions to various problems
- Generally forces an organization of code that works together
- Standardizes interfaces; easier maintenance
- Encourages robustness, testing code

- This does take time so don't always create a module or package
 - If you're going to use a method once, it's not worth putting it in a module
 - If you're using the same methods over and over in (especially in different projects), a module or package makes sense

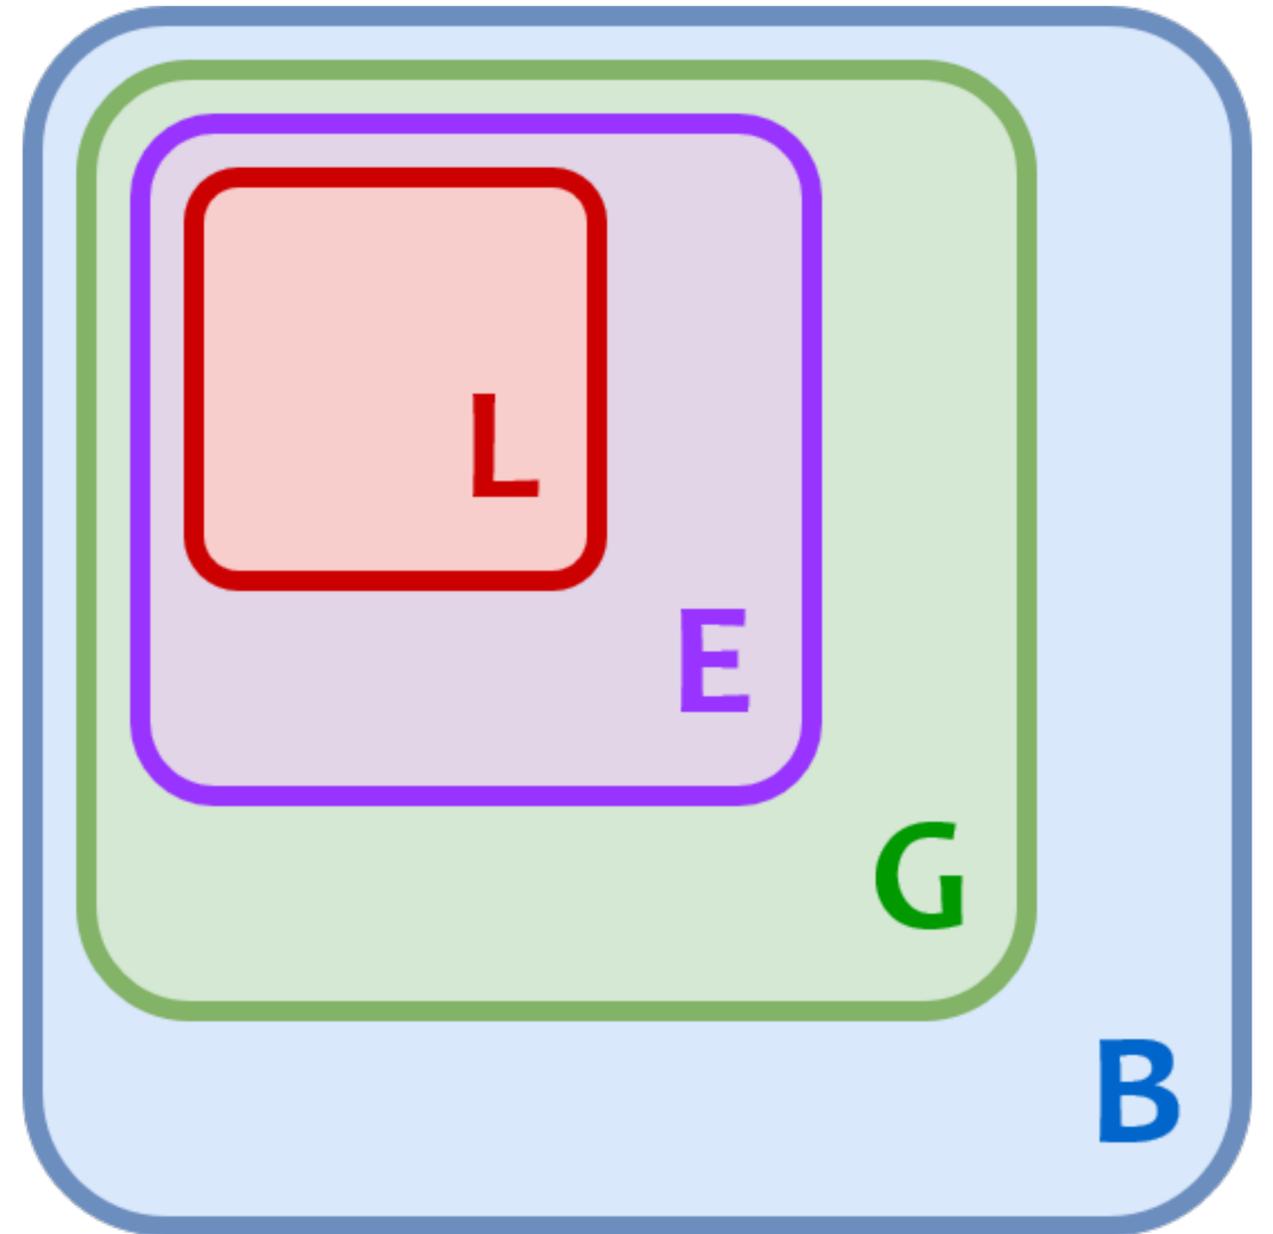

Importing modules

- `import <module>`
- `import <module> as <another-identifier>`
- `from <module> import <identifier-list>`
- `from <module> import <identifier> as <another-identifier>, ...`

- `import` imports from the top, `from ... import` imports "inner" names
- Need to use the qualified names when using `import` (`foo.bar.mymethod`)
- `as` clause **renames** the imported name

Namespaces

- Namespace is basically a dictionary with names and their values
- Accessing namespaces
 - `__builtins__`, `globals()`, `locals()`
- Examine contents of a namespace:
`dir(<namespace>)`
- Python checks for a name in the sequence:
local, enclosing, global, builtins
- To access names in outer scopes, use `global` (global) and `nonlocal` (enclosing) declarations

[RealPython]

Import Conventions

- Avoid wildcard imports like: `from math import *`
- Imports should be on separate lines
 - `import sys`
`import os`
- Sometimes, a conditional import is required
 - `if sys.version_info >= [3,7]:`
`OrderedDict = dict`
`else:`
`from collections import OrderedDict`

Assignment 4

- Assignment covers strings and files
- Reading & writing data to files
- Deals with characters and formatting

Assignment 5

- Scripts, modules, packages
- Command-line program
- Out soon

Reloading a Module?

- If you re-import a module, what happens?
 - `import my_module`
`my_module.SECRET_NUMBER # 42`
 - Change the definition of `SECRET_NUMBER` to 14
 - `import my_module`
`my_module.SECRET_NUMBER # Still 42!`
- Modules are **cached** so they are not reloaded on each import call
- Can reload a module via `importlib.reload(<module>)`
- Be careful because **dependencies** will persist! (Order matters)

Packages

Python Packages

- A package is basically a collection of modules in a directory subtree
- Structures a module namespace by allowing dotted names
- Example:
 - test_pkg/
 - __init__.py
 - foo.py
 - bar.py
 - baz/
 - fun.py
- For packages that are to be executed as scripts, `__main__.py` can also be added

What's `__init__.py` used for?

- Used to be required to identify a Python package (< 3.3)
- Now, only required if a package (or sub-package) needs to run some initialization when it is loaded
- Can be used to specify metadata
- Can be used to import submodule to make available without further import
 - `from . import <submodule>`
- Can be used to specify which names exposed on import
 - underscore names (`_internal_function`) not exposed by default
 - `__all__` list can further restrict, sets up an "interface" (applies to wildcard)

What is `__main__.py` used for?

- Remember for a module, when it is run as the main script, its `__name__` is `__main__`
- Similar idea for packages
- Used as the entry point of a package when the package is being run (e.g. via `python -m`)
 - `python -m test_pkg` runs the code in `__main__.py` of the package

Example

Finding Packages

- Python Package Index (PyPI) is the standard repository (<https://pypi.org>) and pip (pip installs packages) is the official python package installer
 - Types of distribution: source (sdist) and wheels (binaries)
 - Each package can specify dependencies
 - Creating a PyPI package requires adding some metadata
- Anaconda is a package index, conda is a package manager
 - conda is language-agnostic (not only Python)
 - solves dependencies
 - conda deals with non-Python dependencies
 - has different channels: default, conda-forge (community-led)

Installing Packages

- `pip install <package-name>`
- `conda install <package-name>`
- In Jupyter use:
 - `%pip install <package-name>`
 - `%conda install <package-name>`
- Arguments can be multiple packages
- Be careful! Security exploits using package installation and dependencies (e.g. [Alex Birsan](#))

Environments

- Both pip and conda support environments
 - venv
 - conda env
- Idea is that you can create different environments for different work
 - environment for cs503
 - environment for research
 - environment for each project

UV

- Newer package manager
- **Fast.** Written in rust, many optimizations (10-100x faster than pip!)
- Can install python (including alpha releases)
- Integrates with existing ecosystem (`pyproject.toml`, `requirements.txt`)
- Project-based: associates environment with each run (`uv init myproject`)
 - Uses lock file (similar to web programming environments): `uv.lock`
 - Change in execution: `uv run myscript.py`
- Can use standard python tools via temporary environments using `uvx`:
 - `uvx jupyter lab`
- Documentation

pixi

- Combines pip **and conda** package management
- Similar lock files as uv
- Global environment similar to uvx
- Supports multi languages and is multiplatform
- Integrates uv for installing packages from pypi
- Use `pixi shell` to emulate conda/mamba
- [More information](#)

Object-Oriented Programming

Object-Oriented Programming Concepts

- ?

Object-Oriented Programming Concepts

- Abstraction: simplify, hide implementation details, don't repeat yourself
- Encapsulation: represent an entity fully, keep attributes and methods together
- Inheritance: reuse (don't reinvent the wheel), specialization
- Polymorphism: methods are handled by a single interface with different implementations (overriding)

Object-Oriented Programming Concepts

- **Abstraction:** simplify, hide implementation details, don't repeat yourself
- **Encapsulation:** represent an entity fully, keep attributes and methods together
- Inheritance: reuse (don't reinvent the wheel), specialization
- Polymorphism: methods are handled by a single interface with different implementations (overriding)

Vehicle Example

- Suppose we are implementing a city simulation, and want to model vehicles driving on the road
- How do we represent a vehicle?
 - Information (attributes)
 - Methods (actions)

Vehicle Example

- Suppose we are implementing a city simulation, and want to model vehicles driving on the road
- How do we represent a vehicle?
 - Information (attributes): make, model, year, color, num_doors, engine_type, mileage, acceleration, top_speed, braking_speed
 - Methods (actions): compute_estimated_value(), drive(num_seconds, acceleration), turn_left(), turn_right(), change_lane(dir), brake(), check_collision(other_vehicle)

Other Entities

- Road, Person, Building, ParkingLot
- Some of these interact with a Vehicle, some don't
- We want to store information associated with entities in a structured way
 - Building probably won't store anything about cars
 - Road should not store each car's make/model
 - ...but we may have an association where a Road object keeps track of the cars currently driving on it

Object-Oriented Design

- There is a lot more than can be said about how to best define classes and the relationship between different classes
- It's not easy to do this well!
- Software Engineering
- Entity Relationship (ER) Diagrams
- Difference between Object-Oriented Model and ER Model

Class vs. Instance

- A **class** is a blueprint for creating instances
 - e.g. Vehicle
- An **instance** is an single object created from a class
 - e.g. 2000 Red Toyota Camry
 - Each object has its own attributes
 - Instance methods produce results unique to each particular instance

Classes and Instances in Python

- Class Definition:

```
- class Vehicle:  
    def __init__(self, make, model, year, color):  
        self.make = make  
        self.model = model  
        self.year = year  
        self.color = color  
  
    def age(self):  
        return 2026 - self.year
```

- Instances:

```
- car1 = Vehicle('Toyota', 'Camry', 2000, 'red')  
- car2 = Vehicle('Dodge', 'Caravan', 2015, 'gray')
```

Constructor

- How an object is created and initialized
 - ```
def __init__(self, make, model, year, color):
 self.make = make
 self.model = model
 self.year = year
 self.color = color
```
- `__init__` denotes the **constructor**
  - Not required, but usually should have one
  - All initialization should be done by the constructor
  - There is only **one** constructor allowed
  - Can add defaults to the constructor (`year=2021, color='gray'`)

# Instance Attributes

---

- Where information about an object is stored
  - ```
def __init__(self, make, model, year, color):  
    self.make = make  
    self.model = model  
    self.year = year  
    self.color = color
```
- `self` is the current object
- `self.make`, `self.model`, `self.year`, `self.color` are **instance attributes**
- There is **no declaration** required for instance attributes like in Java or C++
 - Can be created in any instance method...
 - ...but good OOP design means they should be initialized in the constructor

Instance Methods

- Define actions for instances
 - `def age(self):`
 `return 2024 - self.year`
- Like constructors, have `self` as first argument
- `self` will be the object calling the method
- Have access to instance attributes and methods via `self`
- Otherwise works like a normal function
- Can also **modify** instances in instance methods:
 - `def set_age(self, age):`
 `self.year = 2024 - age`

Creating and Using Instances

- Creating instances:
 - Constructor expressions specify the name of the class to instantiate and specify any arguments to the constructor (not including `self`)
 - Returns new object
 - `car1 = Vehicle('Honda', 'Accord', 2009, 'red')`
 - `car2 = Vehicle('Dodge', 'Caravan', 2015, 'gray')`
- Calling an instance method
 - `car1.age()`
 - `car1.set_age(20)`
 - Note `self` is not passed explicitly, it's `car1` (instance before the dot)

Used Objects Many Times Before

- Everything in Python is an object!
 - `my_list = list()`
 - `my_list.append(3)`
 - `num = int('64')`
 - `name = "Gerald"`
 - `name.upper()`

Visibility

- In some languages, encapsulation allows certain attributes and methods to be hidden from those using an instance
- public (visible/available) vs. private (internal only)
- Python does not have visibility descriptors, but rather conventions (PEP8)
 - Attributes & methods with a leading underscore (_) are intended as private
 - Others are public
 - You can still access private names if you want but generally **shouldn't**:
 - `print(car1._color_hex)`
 - Double underscores leads to **name mangling**:
`self.__internal_vin` is stored at `self._Vehicle__internal_vin`

Representation methods

- Printing objects:
 - `print(car1)` # `<__main__.Vehicle object at 0x7efc087c6b20>`
- "Dunder-methods": `__init__`
- Two for representing objects:
 - `__str__`: human-readable
 - `__repr__`: official, machine-readable
- ```
>>> now = datetime.datetime.now()
>>> now.__str__()
'2020-12-27 22:28:00.324317'
>>> now.__repr__()
'datetime.datetime(2020, 12, 27, 22, 28, 0, 324317)'
```

[<https://www.journaldev.com/22460/python-str-repr-functions>]

# Representation methods

---

- Car example:

- `class Vehicle:`

- ...

- `def __str__(self):`

- `return f'{self.year} {self.make} {self.model}'`

- Don't call `print` in this method! Return a string

- When using, don't call directly, use `str` or `repr`

- `str(car1)`

- `print` internally calls `__str__`

- `print(car1)`

# Other Dunder Methods

---

- `__eq__ (<other>)`: return `True` if two objects are equal
- `__lt__ (<other>)`: return `True` if object `<` other
- Collections:
  - `__len__ ()`: return number of items
  - `__contains__ (item)`: return `True` if collection contains `item`
  - `__iter__ ()`: returns iterator
- Sequence + dict
  - `__getitem__ (index)`: return item at `index` (which could be a key)
- + More
